We begin with the introduction of a probabilistic framework for modeling financial risk from the perspective of an investor. For a given financial positions, let  $\Omega = \{v_1, v_2, v_3, \dots, v_n\}$  be a finite set of possible future value of this positions, the uncertainty about the future can be represent by a probability space  $(\Omega, F, P)$ .

Then the random variables

$$X : \Omega \rightarrow \mathbb{R}, \quad v \rightarrow X_t(v)$$

denote the position value (pay off) of  $v$  at time  $t$  if the scenario  $v \in \Omega$  is realized.

approach

In general, we can define a **financial risk** as the change in the position-values between two dates  $t_0$  and  $t_1$  (current date is  $t_0 = 0$ ), or as the dispersion of unexpected outcomes due to uncertain events (scenarios  $v$ ). We can quantify the risk of  $X$  by some number  $\rho(X)$ , where  $X$  belongs to a given linear function space  $\mathcal{X}$ , that contains the constant function. ( note that  $\mathcal{X}$  can be identified with  $\mathbb{R}^n$ , where  $n = \text{card}(\Omega)$  ).

## Definition: monetary measure

A function  $\rho : \mathcal{X} \rightarrow \mathbb{R}$  is called a monetary measure of risk if it satisfies the following conditions for all  $X, Y \in \mathcal{X}$

- ▶ Axiom M: Monotonicity  
if  $X \leq Y$ , then  $\rho(X) \geq \rho(Y)$
- ▶ Axiom T: Translation invariance  
if  $m \in \mathbb{R}$ , then  $\rho(X + m) = \rho(X) - m$

- ▶ **Monotonicity:** The risk of a position is reduced if the payoff profile is increased in each state of the World. ( $\rho(X)$  is a decreasing function)
- ▶ **Invariance:** The invariance property suggests that adding cash to a position reduces its risk by the amount of cash added. This is motivated by the idea that the risk measure can be used to determine capital requirements.

## Exemple: capital requirement for risky position $X$

- ▶ if  $\rho(X) > 0$  then regulatory authority requests additional capital to make this position acceptable.
- ▶ if  $\rho(X) < 0$  then the position is already acceptable.

As a consequence for the invariance of  $\rho$  we have

$$\rho(X + \rho(X)) = 0 \text{ and } \rho(m) = \rho(0) - m \quad \forall m \in \mathbb{R}.$$

- ▶ **Monotonicity:** The risk of a position is reduced if the payoff profile is increased in each state of the World. ( $\rho(X)$  is a decreasing function)
- ▶ **Invariance:** The invariance property suggests that adding cash to a position reduces its risk by the amount of cash added. This is motivated by the idea that the risk measure can be used to determine capital requirements.

## Exemple: capital requirement for risky position $X$

- ▶ if  $\rho(X) > 0$  then regulatory authority requests additional capital to make this position acceptable.
- ▶ if  $\rho(X) < 0$  then the position is already acceptable.

As a consequence for the invariance of  $\rho$  we have

$$\rho(X + \rho(X)) = 0 \text{ and } \rho(m) = \rho(0) - m \quad \forall m \in \mathbb{R}.$$

approach

## Remark

$m$  corresponds to the constant function

## Definition: convex risk measure

A monetary risk measure  $\rho : \mathcal{X} \rightarrow \mathbb{R}$  is called a convex measure of risk if it satisfies:

- ▶ Axiom C: (Convexity)

$$\rho(\lambda X + (1-\lambda)Y) \leq \lambda \rho(X) + (1-\lambda)\rho(Y), \text{ for } 0 \leq \lambda \leq 1.$$

**Interpretation:** the convexity property states that the risk of a portfolio is not greater than the sum of the risks of its constituents, that means diversification in a given portfolio does not increase the risk

## Definition: Coherent Risk Measure

A convex measure of risk  $\rho$  is called a coherent risk measure if it satisfies:

- ▶ Axiom PH: Positive Homogeneity

$$\text{If } \lambda \geq 0 \text{ then } \rho(\lambda X) = \lambda \rho(X) \quad \forall X \in \mathcal{X}$$

If a monetary measure of risk  $\rho$  is positively homogeneous, then it is **normalized** ( $\rho(0) = 0$ ), Under the assumption of positive homogeneity, convexity is equivalent to

- ▶ Axiom S: Subadditivity

$$\rho(X + Y) \leq \rho(X) + \rho(Y)$$

- ▶ The subadditivity axiom ensure that the risk of a diversified portfolio is no greater than the corresponding weighted average of the risks of the constituents.
- ▶ Capital requirement for holding company should never be larger than the sum of Capital requirement of all individual subs.
- ▶ subadditivity reflects the idea that risk can be reduced by diversification
- ▶ Subadditivity makes decentralization of risk-management systems possible.

One can separate the set  $\mathcal{X}$  in different subsets :

- ▶  $L_+ = \{X \in \mathcal{X} | X(v) \geq 0 \forall v \in \Omega\}$  (the set of non-negative elements of  $\mathcal{X}$  )
- ▶  $L_- = \{X \in \mathcal{X} | \exists v \in \Omega \text{ s.t. } X(v) < 0\}$  (the set of negative elements of  $\mathcal{X}$ )
- ▶  $L_{--} = \{X \in \mathcal{X} | X(v) < 0 \forall v \in \Omega\}$

For example in case  $n = 2$  ( $\Omega = \{v_1, v_2\}$ ) we can represent  $\mathcal{X}$  in a 2-coordinate system. Where the x-axis represents the measurements of  $x = X(v_1)$  and the y-axis represents the measures of  $y = X(v_2)$ .

Value at Risk

VaR and  
Regulatory  
approach

Depending on its risk policy, the regulator can separate the set  $\mathcal{X}$  into two distinct subset:

1. Acceptable set
2. Unacceptable set

## Definition: Acceptance set

The acceptance set  $A$  is defined as the set of financial positions that are acceptable (from the regulator's point of view) without any additional capital requirement.

As in [Artzner99] we state here some axioms that an acceptance set  $\mathcal{A}$  must satisfy:

- ▶ Axiom A1: The acceptance set  $\mathcal{A}$  contains  $L_+ \subset \mathcal{X}$
- ▶ Axiom A2: The acceptance set  $\mathcal{A}$  does not intersect  $L_{--}$
- ▶ Axiom A3: The acceptance set  $\mathcal{A}$  is convex

The separation of acceptance set  $A$  from unacceptable set can be materialized by the characterization of the boundary of  $A$  (of  $\partial A$ ).

In the case  $n=2$ , we can deduce from the axioms of acceptance set some geometrical properties of the boundary of  $A$  ( $\partial A$ ).

Consider the angle  $\alpha$  in the previous picture, then we get according to the axioms of the acceptance set the following relationships:

- ▶ Axiom A1  $\Rightarrow \alpha \geq 90^\circ$
- ▶ Axiom A2  $\Rightarrow \alpha \leq 270^\circ$

# Relation to Risk Measures I

## Definition: Acceptance set associated to a risk measure

The acceptance set associated to a risk measure  $\rho$  is the set denoted by  $\mathcal{A}_\rho$  and defined by

$$\mathcal{A}_\rho = \{X \in \mathcal{X} : \rho(X) \leq 0\} \quad (*)$$

## Definition: Risk measure associated to an acceptance set

The risk measure associated to the acceptance set  $\mathcal{A}$  is the mapping from  $\mathcal{X}$  to  $\mathbb{R}$  denoted by  $\rho_{\mathcal{A}}$  and defined by

$$\rho_{\mathcal{A}}(X) = \inf\{m \in \mathbb{R} \mid X + m \in \mathcal{A}\} \quad (**)$$

The amount  $m$  may be interpreted as the required regulatory capital to cover the position's risk

The previous graphic illustrate the relationsheap between the acceptance set  $\mathcal{A}$  (namely the boundary  $\partial\mathcal{A}$  of  $\mathcal{A}$ ) and measure of the risk in the case  $n=2$ . In this example we can see that initialy  $X_1(1, -2.34)$  does not belong to the acceptance set, it is also unacceptable from the perspective of the regulator, but we can make it acceptable, according to the definiton (\*\* ) by Adding some cash  $m = 1$  (or hihger than 1). The new position  $X_2 = X(1, -2.34) + m(1, 1) = (2, -1.34)$  is on the boundary  $\partial\mathcal{A}$  of the acceptance set and therefore acceptable.

Résumé

### Example of Monetary Measure of Risk

Worst-Case Risk  
Measure  
Value at Risk

### VaR and Regulatory approach

- ▶  $\rho_{\mathcal{A}}$  is a convex risk measure if and only if  $\mathcal{A}$  is convex.
- ▶  $\rho_{\mathcal{A}}$  is positively homogeneous if and only if  $\mathcal{A}$  is a cone. In particular,  $\rho_{\mathcal{A}}$  is coherent if and only if  $\mathcal{A}$  is a convex cone.
- ▶  $\mathcal{A}_{\rho}$  is clearly convex if  $\rho$  is a convex measure of risk

Assume that  $\mathcal{A}_{\rho}$  is a non-empty subset of  $\mathcal{X}$  which satisfies  $\rho_{\mathcal{A}} > -\infty$  and  $X \in \mathcal{A}, Y \in \mathcal{X}, Y \geq X \Rightarrow Y \in \mathcal{A}$  Then:

- ▶  $\rho_{\mathcal{A}}$  is a monetary measure of risk.
- ▶ If  $\mathcal{A}_{\rho}$  is a convex set, then  $\rho_{\mathcal{A}}$  is a convex measure of risk.
- ▶  $\rho_{\mathcal{A}}$  is a coherent measure of risk if  $\mathcal{A}_{\rho}$  is a convex cone.

- ▶ Therefore we need a appropriate monetary risk measure for the unacceptable position (downsid risk).
- ▶ Such a measure  $\rho$  should have the following properties.
  - ▶  $\rho$  is a decreasing function of  $X$
  - ▶  $\rho$  is stated in the same units as  $X$
  - ▶  $\rho$  is positive if  $X$  is non-acceptable
  - ▶  $\rho$  is a coherent risk measure

# Exemple I : Worst-Case Risk Measure

## Definition

The worst-case risk measure  $\rho_{max}$  defined by

$$\rho_{max}(X) = - \inf_{v \in \Omega} X(v) \quad \forall X \in \mathcal{X}$$

- ▶ The value of  $\rho_{max}$  (Capital requirements) is the least upper bound for the potential loss which can occur in any scenario.
- ▶  $\rho_{max}$  is a coherent measure of risk
- ▶ Any normalized monetary risk measure  $\rho$  on  $\mathcal{X}$  satisfies
$$\rho(X) \leq \rho_{max}(X)$$
It is also the most conservative measure of risk.
- ▶ PML (Probable maximum loss) could be seen as equivalent in insurance

Measure  
Value at Risk

VaR and  
Regulatory  
approach

## Example II: Value at Risk

Suppose that we have a probability measure  $P$  on  $(\Omega, \mathcal{F})$ . In this context, a position  $X$  is often considered to be acceptable if the **probability of a loss** is bounded by a given level  $\lambda \in (0, 1)$  that means:

$$P[X < 0] \leq \lambda.$$

The corresponding monetary risk measure (necessary capital) is called Value at Risk (VaR)

### Definition: Value at Risk

$$\text{VaR}_\lambda A(X) = \inf \{m \in \mathbb{R} \mid P[m + X < 0] \leq \lambda\}$$

- ▶ Value-at-Risk refers to a quantile of the loss distribution
- ▶ Value-at-Risk is positively homogeneous, but in general it is not convex

VaR and  
Regulatory  
approach

VaR is the standard regulatory MMR for Bank sector for market-risk(MR). The internal model (IM) proposes the following formula to calculate the market-risk-capital at day  $t$ ,

$$RC_{IM}^t(MR) = \max \left\{ VaR_{0.99,10}^t ; \frac{k}{60} \sum_{i=1}^{60} VaR_{0.99,10}^{t-i+1} \right\} + RC_{SR}^t$$

where

- ▶  $VaR_{0.99,10}^t$  stands for a 10-day VaR at the 99% confidence level, calculated on day  $t$ .
- ▶ RC= Risk Capital
- ▶ MR = Market Risk and SR = Specific Risk
- ▶  $k \in [3, 5]$  Stress Factor
