

Formale Methoden

WS 2007/2008 – Übungsblatt 2

6. November 2007
Ausgabe: 9. November 2007

Aufgabe 1. Ein Contract

Erläutern Sie die Prinzipien des DbC/PbC an folgendem Beispiel:

```

...
template <class T>
set<T> operator+(const set<T>& s, const T& e){
    ...
};

...
template <class T>
set<T> operator-(const set<T>& s, const T& e){
    ...
};

class mydictionary{

    vector<KEY>* keys;
    vector<VALUE>* values;
    unsigned int count;

public:
    //////////// basic queries:

    unsigned int get_count() const;           // number of key/value-pairs in dict.

    bool has(const KEY& k) const;             // key in dictionary?

    VALUE value_for(const KEY& k) const;       // lookup value for key

    //////////// class invariant:
private:

```

```

    virtual bool invariant() const;
public:

    ////////////////// derived queries:
    // not yet necessary

    ////////////////// constructors and destructors:

    mydictionary();
    ~mydictionary();

    ////////////////// copy constructor

    mydictionary(const mydictionary<KEY, VALUE>& s);

    ////////////////// deactivate operator=

private:
    mydictionary& operator=(const mydictionary<KEY, VALUE>& s);
public:

    ////////////////// (pure) modifiers

    void put(const KEY& k, const VALUE& v);           // put key/value-pair in dict.

    void remove(const KEY& k);                         // remove key/value-pair

};

...

template<class KEY, class VALUE>
unsigned int mydictionary<KEY, VALUE>::get_count() const{
    REQUIRE( invariant() );
    ...
};

...

template<class KEY, class VALUE>
bool mydictionary<KEY, VALUE>::has(const KEY& k) const {
    REQUIRE( invariant() );
    ...
    ENSURE( /* consistent with count */ (get_count() != 0) || ! result);
    ENSURE(" get_count() == # { k in KEY | has(k) } ");
    ...
};

...

template<class KEY, class VALUE>
VALUE mydictionary<KEY, VALUE>::value_for(const KEY& k) const{

```

```

REQUIRE( invariant() );
REQUIRE(/* key in dict. */      has(k));
...
};

...
template <class KEY, class VALUE>
bool mydictionary<KEY, VALUE>::invariant() const{
...
};

...
template<class KEY, class VALUE>
mydictionary<KEY, VALUE>::mydictionary(){
...
    ENSURE(invariant());
    ENSURE(count == 0);
};

...
template<class KEY, class VALUE>
mydictionary<KEY, VALUE>::~mydictionary(){
    REQUIRE( invariant() );
    ...
};

...
template<class KEY, class VALUE>
mydictionary<KEY, VALUE>::mydictionary(const mydictionary<KEY, VALUE>& s){
...
    ENSURE(count == s.count);
    ENSURE(A(int i=1, i<=count, i++, keys->at(i-1) == s.keys->at(i-1)));
    ENSURE(A(int i=1, i<=count, i++, values->at(i-1) == s.values->at(i-1)));
...
    ENSURE(invariant());
};

...
template<class KEY, class VALUE>
void mydictionary<KEY, VALUE>::put(const KEY& k, const VALUE& v)
DO
    REQUIRE(/* key not in dict. */ ! has(k));
    ID(unsigned int count_old=get_count());
    ID(set<KEY> old_keys(keys->begin(), keys->begin()+count_old));
...
    ENSURE(/* count incremented */ get_count() == count_old + 1);
    ENSURE(/* key in dict. */ has(k) );
    ENSURE(/* correct value */ value_for(k) == v);
    ID(set<KEY> new_keys(keys->begin(), keys->begin()+count));
    ENSURE(old_keys + k == new_keys);
    ENSURE("Framebedingung: fuer alle k in old_keys: value_for(k) == ...");
END;
...
template<class KEY, class VALUE>

```

```

void mydictionary<KEY, VALUE>::remove(const KEY& k)
DO
    REQUIRE(/* key in dict. */ has(k));
    ID(unsigned int count_old = get_count());
    ID(set<KEY> old_keys(keys->begin(), keys->begin()+count_old));
    ...
    ENSURE(/* count decremented */ get_count() == count_old - 1);
    ENSURE(/* key not in dict. */ ! has(k));
    ...
    ID(set<KEY> new_keys(keys->begin(), keys->begin()+count));
    ENSURE(old_keys - k == new_keys);
    ENSURE("Framebedingung");
END;
...
int main(){
    ...
}

```

Aufgabe 2. Subcontracting

Erläutern Sie, warum die Nachbedingung eines Modifikators einer „is-a“ UnterkLASSE im Falle der Gültigkeit der Vaterklassenvorbedingung nicht schwächer sein darf als die Vaterklassennachbedingung, jedoch andernfalls „beliebig“ sein darf:

```

----- Fussgaengerbruecke
QUERIES
    MaxLast : REAL
    AktLast : REAL
INVARIANTS
    MaxLast >= 7500
    AktLast <= MaxLast
ACTIONS
    ueberquereBruecke( IN gew : REAL,
                        OUT Guthaben : INTEGER )
PRE
    gew + AktLast <= MaxLast
    gew <= 200
    Guthaben >= 2
POST
    AktLast = OLD(AktLast) + gew
    Guthaben = OLD(Guthaben) - 2
    verlasseBruecke( IN gew : REAL )
    ...

```

sowie ein Subcontract:

```

----- Autobruecke
QUERIES

```

```

        MaxLast : REAL
        AktLast : REAL
INVARIANTS
        MaxLast >= 800000
        AktLast <= MaxLast
ACTIONS
    ueberquereBruecke( IN gew : REAL,
                        OUT Guthaben : INTEGER )
PRE
    gew + AktLast <= MaxLast
    gew <= 20000
    Guthaben >= 20
POST
    AktLast = OLD(AktLast) + gew
    OLD(gew) <= 200      IMPLIES Guthaben = OLD(Guthaben) - 2
    NOT OLD(gew) <= 200 IMPLIES Guthaben = OLD(Guthaben) - 20
verlasseBruecke( IN gew : REAL )
    ...

```

Aufgabe 3. *Redesign Sparbuch*

Designen Sie das Sparbuch aus Übungsblatt 1 neu nach den Prinzipien des DbC/PbC.

Aufgabe 4. *Ein UML-Modell*

Konzipieren und konstruieren Sie ein Klassenmodell im Umfeld Bestellung/Lieferschein/Rechnung.
